

for loop:

- ↳ Initialisation, data type
- ↳ Condition (n value) ex: $(i \leq 10)$
- ↳ Increment $(i++)$ & decrement $(i--)$

Process

Initialisation
Condition

Statement print

Check (Incr & dec)

Condition (check)

Print (until the loop end)

Again & Again I want what I've added were print
I have to give the print statement Inside the for loop (continue) loop end

Whole value added Ans I've to give the print statement
outside of the loop.

Decrement loop

$(i--)$ for decrement.

starts from High value ($5 \xrightarrow{\text{st}} 0 \xrightarrow{\text{end}}$)

Initial starts from higher value.

Odd (or) even

use for loop inside the Condition statement
for loop kulla Condition st. use panam.

for odd $(i \% 2) (\%)$

for even $(i == j) (==)$

$(i = 1 + 2)$ will print the odd num without if statement

$(i = 0 + 2)$ will print the even num without if statement

Pattern Printing Using for loop

$(i \times j)$ pattern (matrix)

first for loop represent the row (i)

Second for loop represent the column (j)

Column value will decide the printing value. if the

Condition is wrong the pattern will not come as expect.

To find the solution of the condition, helps to improve logical thinking.

Until we analyse the pattern of i condition, completely, can't define the value of j condition.

↳ Print = continuous line

↳ Print $\ln$ = new line

"\t" = for space (tab)
